The pore structure of hardened cement paste is multiscale and multicomponent. Previous literature studies devise the pore structure of hardened cement paste into four parts: gel pores ( $<10$  nm), small capillary pores (10–100 nm), large capillary pores (100–1000 nm), and air holes ( $>$ several  $\mu\text{m}$ ) . In fact, many methods have been applied to characterize the pore structure of hardened cement paste or concrete.

One example is introduction of a large number of air voids in the matrix and optimization of their pore structure.

Cement-based materials generated in this fashion have relatively low density, poor mechanical performance or poor thermal insulation performance , , .

Thus, to boost the application of cement-based thermal insulation materials, further improving the thermal insulation performance at a fixed density grade is needed.

The permeability of cement-based material is closely related to the structure of pores, but the results on the structure of pore mainly confine to that obtained by MIP. In the MIP test, sample needs to be cut into small particles and the structure of pores may be destroyed. SAP or air pore may also be opened.

The pore structure (i.e. total pore volume, surface area and pore-size distribution curves) was measured using mercury porosimetry and nitrogen sorption. Hydrated portland cement (type I) of water-cement (w/c) ratios 0.3, 0.4 and 0.6 by weight was analyzed at three degrees of hydration (i.e., 30%, 50% and 80%; 70% for the 0.3 w/c

The pore structure of cement-based materials contains air voids, capillary pores, and gel pores, and the pores are randomly sized, arranged, and connected . It is a well-known fact that porosity is one of the key parameters which directly affect the strength and durability of cement-based materials [ 6 , 7 ].
